

Introduction to Perovskite Solar Cells

Overview

Perovskite solar cells are one of the most active areas of renewable energy research at present. The primary research objectives are to improve their optoelectronic properties and long-term stability in different environments. The importance of sustainable electric power generation cannot be overemphasised, as it is a key component of a sustainable future. Planar perovskite solar cells (PSCs) can be made in either a regular n-i-p structure or an inverted p-i-n structure (see Fig. 1 for the meaning of n-i-p and p-i-n as regular and inverted arch). Historically, the term perovskite refers to a naturally occurring mineral made of calcium titanium oxide (CaTiO_3) (Fig. 7), discovered in the Ural Mountains by scientists Gustav Rose and Heinrich Strunz. UV-Vis absorbance analysis is a non-destructive method of characterisation that describes the optical absorption properties of a material. The fundamental mechanism by which perovskite solar cells convert light into electricity is through the generation of electron-hole pairs. High-quality perovskite thin films are crucial for the development of high-performing perovskite photovoltaic devices. In this context, that means the film will have uniform morphology.
